ABSTRACT

Prometheus is an agent-oriented software engineering methodology. The Prometheus Design Tool (PDT) is a software tool that supports a designer who is using the Prometheus methodology. PDT has recently been extended with two significant new features: support for Agent UML interaction protocols, and code generation.

Categories and Subject Descriptors

General Terms

Design

Keywords

Agent Oriented Software Engineering, Design Tools, Agent UML

1. PROMETHEUS

Prometheus [9] is a software engineering methodology for the design of agent systems. It comprises a set of concepts, a process, and notations for capturing the requirements and design of the system. The process described in the Prometheus book [9] includes both a high level description of the phases of the methodology, and, importantly, detailed steps and techniques for carrying out the various high level steps. For example, one high level step in the overall process is identifying the agent types in the system, and the Prometheus methodology describes how this is done by grouping roles, considering coupling and cohesion, using a data coupling and an agent acquaintance diagram, etc.

Prometheus consists of three phases (depicted in figure 1):

- **System specification**: in which the goals of the system are identified, and detailed scenarios consisting of sequences of steps are developed.
- **High-level (architectural) design**: in which the agent types that will exist in the system are defined by combining roles, the overall structure of the system is described using a system overview diagram, and interaction protocols are used to capture the dynamics of the system in terms of legal message sequences.
- **Detailed design**: in which the internals of each agent are developed in terms of capabilities, events, plans and data. Process diagrams are used as a stepping stone between interaction protocols and plans.

2. PROMETHEUS DESIGN TOOL

The Prometheus Design Tool (PDT) is a freely available tool, running under Java 1.5, which supports the software designer who is using the Prometheus methodology. PDT provides graphical support for the design phases of the methodology, allowing the designer to enter and edit diagrams and descriptors for entities. PDT also enforces certain constraints (e.g. that an action performed by an agent in the system overview diagram must also appear in the relevant agent overview diagram) and also checks the design for various consistency conditions.

Two recent additions to PDT (which are highlighted in figure 1) are support for Agent UML interaction protocols, and the ability to generate code.

2.1 Support for AUML in PDT
As can be seen in figure 1, one of the steps in the architectural design is developing interaction protocols that capture the dynamics of the system, in terms of messages between agents. Although a wide range of notations could be used for capturing interaction protocols, we choose to adopt the widely-used Agent UML (AUML\footnote{http://www.auml.org}) notation [6], specifically its sequence diagram notation, which has also been adopted by other methodologies, such as Gaia and Tropos.

Until recently PDT lacked complete support for capturing interaction protocols, and was only able to capture sequences of messages. This has been remedied with the addition of support for Agent UML. The new PDT allows a designer to specify AUML interaction protocols using a textual notation \cite{11}. The traditional AUML graphical rendition is automatically generated, and the tool also propagates information from the protocol to the rest of the design. For example, if a protocol indicates that an agent sends a message, then that message is added to the agent’s interface in the system overview and agent overview diagrams.

2.2 Code Generation in PDT
Once a design for an agent system has been developed, the design needs to be implemented. PDT has recently been extended with the ability to generate skeleton code in the JACK agent-oriented programming language \cite{2}. The code generator extension to PDT also maintains synchronisation between the generated code and the design when either of them changes.

3. RELATED WORK
Of the many agent-oriented methodologies that have been proposed, not many have well-developed CASE tools. Two methodologies that do have publicly available and well-developed support tools are MaSE \cite{4}, with agentTool\footnote{http://sra.itc.it/tools/taom4e/}, and Tropos \cite{1}, with TAOM4E.\footnote{http://sra.itc.it/tools/taom4e/} Other existing tools include the REBEL tool\footnote{http://www.cis.msu.oz.au/agentlab/}, supporting the ROADMAP methodology \cite{7}, and the PTK tool\footnote{http://mozart.csai.unipa.it/passi/}, supporting the PASSI methodology \cite{3}. Additionally, the JACK Design Environment (JDE\footnote{http://www.agent-software.com.au}) provides design diagrams, but does not provide support for a full methodology.

4. DISCUSSION
The Prometheus methodology has been taught to undergraduates since 2001, and our experiences in teaching this course led to the creation of an initial prototype tool in 2002, with the current Java-based tool being developed in the first half of 2003. Since 2003 it has been actively enhanced, extended, and debugged.

Key areas for future work for PDT include enabling interchange of (relevant parts of) designs with the ISLANDER tool for designing electronic institutions \cite{5}; integrating work on debugging using design models \cite{10}; support for importing and exporting parts of the design, allowing design by a team of developers; and integrating support for testing agent systems, with the focus on unit testing.

5. ACKNOWLEDGEMENTS
We would like to thank the many people who have worked on PDT over the years: Christian Andersson, Anna Edberg, Claire Hennekm, Jason Khalilouf, Ian Mathieson, Mikhail Peretretchikov, Aman Sahani, Shankar Srikanthaiah, and anyone else we may have forgotten.
